

Regardless of the low or high LCOS indication, the "variable EP scenario" shows that all included energy storage technologies are valuable. As noted earlier, we define a technology as valuable if it reduces the total system costs. This is the case if a technology is part of an optimised energy system.

In comparison to the low carbon cost scenario of \$20/ton, the scenario with a cost of \$100/ton shows a 6% increase in carbon emission reduction. Consequently, the carbon emission value and energy storage value also rise by 89% and 79%, respectively, displaying a notably improved effect.

In this article, the investment cost of an energy storage system that can be put into commercial use is composed of the power component investment cost, energy storage media investment cost, EPC cost, and BOP cost. The cost of the investment is calculated by the following equation: (1) CAPEX = $C_P \cdot Cap + C_E \cdot Cap \cdot Dur + C_{EPC} + C_{BOP}$

We categorise the cost analysis of energy storage into two groups based on the methodology used: while one solely estimates the cost of storage components or systems, the other additionally considers the charging cost, such as the levelised cost approaches.

This value could increase to 40 percent if energy capacity cost of future technologies is reduced to \$1/kWh and to as much as 50 percent for the best combinations of parameters modeled in the space. For purposes of comparison, the current storage energy capacity cost of batteries is around \$200/kWh.

This inverse behavior is observed for all energy storage technologies and highlights the importance of distinguishing the two types of battery capacity when discussing the cost of energy storage.
