Large 50 Mvarthree-phaseiron-core loading inductor at a utility substation An inductor usually consists of a coil of conducting material, typically insulated copper wire, wrapped around a coreeither of plastic (to create an air-core inductor) or of a ferromagnetic(or ferrimagnetic) material; the latter is called an "iron core" inductor.

For example, a vacuum and air have a relative permeability of one and for an iron core it is around 500, so we can say that the field strength of an iron core is 500 times stronger than an equivalent hollow air coil and this relationship is much easier to understand than 0.628×10-3 H/m, (...

All other factors being equal, greater coil area (as measured looking lengthwise through the coil, at the cross-section of the core) results in greater inductance; less coil area results in less inductance. Explanation: Greater coil area presents less opposition to the formation of magnetic field flux, for a given amount of field force (amp-turns).

turns ratio. Energy storage in a transformer core is an undesired parasitic element. With a high permeability core material, energy storage is minimal. In an inductor, the core provides the flux linkage path between the circuit winding and a non-magnetic gap, physically in series with the core. Virtually all of the energy is stored in the gap.

The formula for energy storage in an inductor reinforces the relationship between inductance, current, and energy, and makes it quantifiable. Subsequently, this mathematical approach encompasses the core principles of electromagnetism, offering a more in-depth understanding of the process of energy storage and release in an inductor.

Energy storage. Energy storage is usually not desired in transformers, it is however often the primary purpose of a inductor. It is among other things used in the buck-boost converter, and the flyback converter. The energy stored in a inductor is given by: begin{equation} E = frac{1}{2} cdot L cdot I^2 end{equation}

AC Resistance: Iron core inductors have a higher AC resistance than inductors with other types of cores, which can cause losses at high frequencies. The following are some applications of iron core inductors: Iron core inductors are used in power converters to store energy in their magnetic field and reduce voltage fluctuations.

Similarly, an inductor has the capability to store energy, but in its magnetic field. This energy can be found by integrating the magnetic energy density, $[u_m = dfrac\{B^2\}\{2mu_0\}]$ over the appropriate volume. To understand where this formula comes from, let's consider the long, cylindrical solenoid of the previous section.

An inductor that has a central core that is composed of iron would have a higher inductance than an inductor that has a central core of air because iron has a higher magnetic permeability than air.

By resisting change in current, the filter inductor essentially accumulates stored energy as an AC current crests each cycle, and releases that energy as it minimizes. Power inductors require the presence of an air gap within the core structure. The purpose of the gap is to store the energy, and to prevent the core from saturating under load.

Where, W = work done which is equal to energy, L = inductance, and I = current ; The energy stored in the magnetic field is generated in the inductor due to the current flow. Hence, the expression for energy stored in an inductance coil carrying current is W = 1.2 LI 2.
