

o Soft saturation: the inductance reduces progressively. This is the case for power inductors with winding on a powdered core. When examining inductor saturation the inductance vs current curve is preferable to the value of the saturation current. Figure 1. An inductor is a device whose purpose is to store and release energy. A filter inductor uses this capability to smooth the current through it and a two-turn flyback inductor employs this energy storage in the flyback converter in-between the pulsed current inputs. When compared to the saturation flux density of the magnetic material, it can be determined whether the designed inductance is at risk of saturation. This method is suitable for designing circuits by directly using existing inductors. Different circuit topologies have different formulas for inductor current calculation.

This energy is stored in inductors, which often are subject to a substantial dc current flow. This mode of operation requires taking measures to avoid saturation of the inductor's core, which may often be detrimental to the device it is used in. The reference explains how to design such an inductor based on a distributed-gap magnetic. Usage of

Toroidal inductors. The prior discussion assumed μ_r filled all space. If μ_r is restricted to the interior of a solenoid, L is diminished significantly, but coils wound on a high- μ_r toroid, a donut-shaped structure as illustrated in Figure 3.2.3(b), yield the full benefit of high values for μ_r . Typical values of μ_r are ~5000 to 180,000 for iron, and up to 10^6 for special ...

Energy storage inductor saturation

Rawbrowb's answer doesn't explain the actual mechanism by which saturation occurs, which is a fairly easy to understand. It helps to first understand how materials generate magnetic fields. A simple way to think of this is as each atom being a small loop of current which generates a magnetic field.

In common inductors, the nominal reluctance, is typically dominated by the air-gap. The cores in the saturation-gap topology do not have physical air-gap, but an equivalent air-gap reluctance is achieved by the saturation of the SG. The saturation-gap topology is been documented to reduce the size of power inductors, operating in DC applications.

Unlike a forward-topology transformer (where the primary and secondary windings are conducting at the same time), the flyback transformer must store energy during the primary switch on-time, delivering it to the load during the primary switch off-time.

One rapid way to determine this is to measure the current flowing into the inductor. In fact, when the inductor enters saturation the inductance drops, which means that the inductor current slope gets steeper. See Equation 1: Figure 2 shows the inductor current waveform of a boost converter without saturation.

family. They all function by taking energy from the electrical circuit, storing it in a magnetic field, and subsequently returning this energy (minus losses) to the circuit. A flyback transformer is actually a multi-winding coupled inductor, unlike the true transformers discussed in Section 4, wherein energy storage is

If we increase the length of the gap, the slope of the B-H curve reduces further, leading to an even greater energy storage capacity. Most of the energy in a gapped inductor is actually stored in the air gap. Choosing the Gap Length and Number of Turns. We saw that the air gap increases the saturation current but lowers the inductance.

Inductor core saturation can often be observed directly in the converter current waveform where di/dt is inversely proportional to inductance. As inductance drops due to core saturation, the current slope increases rapidly. This can cause noise and damage to other components.

We have a core of some nominal energy storage capacity, independent of the winding we put around it; the question, then, is what impedance -- what ratio of voltage to current -- the circuit needs. The turns count is the transformer matching ratio for an inductor to the circuit. And when the inductor saturates, that ratio changes.

The property of inductance preventing current changes indicates the energy storage characteristics of inductance [11]. When the power supply voltage U is applied to the coil with inductance L , the inductive potential is generated at both ends of the coil and the current is generated in the coil. When the inductor enters saturation, it can store less energy and the ripple current increases - meaning that the efficiency will be reduced. At this point, the inductor is behaving more like a resistor than an inductor.
