A brief background: the underlying principle of the flywheel energy storage system--often called the FES system or FESS--is a long-established basic physics. Use the available energy to spin up a rotor wheel (gyro) via a motor/generator (M/G), which stores the energy in the rotating mass (Figure 1). Electronics is also required for the motor ...

Flywheel Housing: The flywheel housing is solid and sits outside the flywheel. The flywheel is the part of the engine that turns and supplies power to the alternator.; Springs: The flywheel consists of two-phase springs bent in parallel. The outer arc is adjusted to raise the spring when the engine is running. The soft outer bow spring is only used to improve the unsafe resonance frequency ...

The amount of energy stored,  $E$ , is proportional to the mass of the flywheel and to the square of its angular velocity. It is calculated by means of the equation (1)  $E = \frac{1}{2} I \omega^2$  where  $I$  is the moment of inertia of the flywheel and  $\omega$  is the angular velocity. The maximum stored energy is ultimately limited by the tensile strength of the flywheel material.

Flywheel energy storage (FES) works by accelerating a rotor (flywheel) to a very high speed and maintaining the energy in the system as rotational energy. The energy is converted back by slowing down the flywheel. Most FES systems use electricity to accelerate and decelerate the flywheel, but devices that directly use mechanical energy are being developed.
