Flywheel energy storage (FES) works by accelerating a rotor (flywheel) to a very high speed and maintaining the energy in the system as rotational energy. The energy is converted back by slowing down the flywheel. Most FES systems use electricity to accelerate and decelerate the flywheel, but devices that directly use mechanical energy are being developed.

The core element of a flywheel consists of a rotating mass, typically axisymmetric, which stores rotary kinetic energy  $E$  according to (Equation 1)  $E = \frac{1}{2} I \omega^2$  [J], where  $E$  is the stored kinetic energy,  $I$  is the flywheel moment of inertia [ $\text{kgm}^2$ ], and  $\omega$  is the angular speed [rad/s]. In order to facilitate storage and extraction of electrical energy, the rotor ...

Where,  $K$  is the radius of gyration for the flywheel. Now, Energy stored in the flywheel can be given by:  $E = \frac{1}{2} \rho \pi K^2 \omega^2$ . Where;  $C_s$  is the coefficient of viscosity for the flywheel i.e  $(N_1 - N_2)/N$ . How Can We Use Flywheels To Determine Running Direction? A flywheel can be little handy determining the running direction of an engine.

Flywheel Energy Storage (FES) systems refer to the contemporary rotor-flywheels that are being used across many industries to store mechanical or electrical energy. Instead of using large iron wheels and ball bearings, advanced FES systems have rotors made of specialised high-strength materials suspended over frictionless magnetic bearings ...

The simple concept is the momentary storage of the kinetic energy from the engine in revving up the flywheel as the vehicle decelerates instead of depleting it as heat in the brake pads. This energy would allow modern cars to disengage the engine for long waits (idling at a traffic light, for example) and be stored in flywheels mounted on drive ...

The flywheel energy storage system (FESS) is one such storage system that is gaining popularity.
