Data Center Backup Energy. For decades diesel-powered generators have served as a primary backup power source to the public grid.

TES Tank Sized for 4 hours of full cooling capacity storage as compared to 10 to 15 minutes of current common practice. i.e. if a data center with IT load of 4,000 kw would typically require 5,200 to 5,600 KW (1.3 to 1.4 x IT load) of cooling capacity and hence the thermal storage capacity should be 4 Hrs. x 5,600 kw = 22,400 kwh or 6,370 Ton-Hr.

Initiatives such as using liquid to cool the chips instead of air are expected to make modest energy savings. But forecasts still expect data centers' demand for power to as much as double by 2026, according to the International Energy Association, thanks in part to the demands of artificial intelligence.

First, most data centers are sited with backup energy storage systems to ensure high uptime requirements are met. This backup can be dispatched to offset a data center's load when grid conditions become tight, thus creating a load that is, in effect, highly responsive.

To effectively use the generated renewable energy, data centers are increasingly building their own microgrids, which act as localized control systems to manage the integration of renewable energy generation, energy storage, and the data center's power requirements, while addressing the complexity of integrating with the wider electrical grid.
