The air-to-water heat pump extracts that heat and raises it to a usable temperature level for immediate building heating. If the building is already warm enough, the thermal energy storage tanks can absorb the heat by melting ice. That energy is now captured and stored for later use, generally in the morning before interior heat has accumulated.

Sensible energy storage works on the principle that the storage material should have a high specific heat, is big in size and there should be a bigger temperature difference between the heat transfer fluid (HTF) and the storage material [4]. Because of those requirements, sensible energy storage systems suffer from a low energy density and also ...
