In this case, the discharge rate is given by the battery capacity (in Ah) divided by the number of hours it takes to charge/discharge the battery. For example, a battery capacity of 500 Ah that is theoretically discharged to its cut-off voltage in 20 hours will have a discharge rate of $500 \text{ Ah}/20 \text{ h} = 25 \text{ A}$.

However, it is more common to specify the charging/discharging rate by determining the amount of time it takes to fully discharge the battery. In this case, the discharge rate is given by the battery capacity (in Ah) divided by the number of hours it takes to charge/discharge the battery.

The Depth of Discharge (DOD) of a battery determines the fraction of power that can be withdrawn from the battery. For example, if the DOD of a battery is given by the manufacturer as 25%, then only 25% of the battery capacity can be used by the load.

How to calculate the energy storage discharge

1. Rate of Discharge. The rate of discharge refers to the current that can be drawn from the battery at any given time. A higher rate of discharge enables greater energy storage capacity in the battery.

Then, you can calculate the internal resistance using Ohm's law. However, calculating the battery internal resistance this way takes time as you can only measure the OCV when the battery is at rest. Alternatively, you can calculate the internal resistance through Joule's law by measuring the energy generated by the battery during operation.
