

Hydrogen storage tank

This paper provides a comprehensive review of common on-board hydrogen storage tanks, possible failure mechanisms and typical manufacturing methods as well as their future development trends.

There are many different hydrogen storage options being investigated, trialed, and used within the energy industry. On-land storage of hydrogen uses compressed pressure vessels for gas, cryogenic storage for liquid hydrogen, and the blending of hydrogen into natural gas to be stored in current pipeline systems.

Liquid hydrogen Tank at NASA Kennedy Space Center Several methods exist for storing hydrogen. These include mechanical approaches such as using high pressures and low temperatures, or employing chemical compounds that release H₂ upon demand.

Physical storage is the most mature hydrogen storage technology. The current near-term technology for onboard automotive physical hydrogen storage is 350 and 700 bar (5,000 and 10,000 psi) nominal working-pressure compressed gas vessels--that is, "tanks";

Gaseous Storage Systems. Cylinders - Hydrogen cylinders should be stored outside at a safe distance from structures, ventilation intakes, and vehicle routes, even while in use. Best practices call for compressed hydrogen bottles supplying a manifold to be located outside, with brazed/welded lines to connect to indoor equipment.

On-site hydrogen storage is used at central hydrogen production facilities, transport terminals, and end-use locations. Storage options today include insulated liquid tanks and gaseous storage tanks. The four types of common high pressure gaseous storage vessels are shown in the table.

Hydrogen storage systems - Tanks. Rheinmetall's 700 bar Hydrogen Pressure Type IV tank system represents a cutting-edge solution for high-pressure hydrogen storage, also available at 350 bar upon request.

Storage of hydrogen as a gas typically requires high-pressure tanks (350-700 bar [5,000-10,000 psi] tank pressure). Storage of hydrogen as a liquid requires cryogenic temperatures because the boiling point of hydrogen at one atmosphere pressure is -252.8°C.
