Particularly, heat exchanger configurations such as a packed bed for sensible and latent heat storage, bulk storage for sensible and latent storage, and storage in modules are discussed. Further discussion was done on storage in modules such as flat plate module, shell, tube (pipe module), shell and tube (cylinder module).

Heat storage tanks and heat exchangers are the most frequent solutions in active TES systems. The heat source comes from the Sun, biomass boiler or heat pump and is stored in the storage elements. Various solutions for energy storage materials are developed, such as bulk storage tanks, packed beds, or modules.

As the heat transfer fluid (HTF) moves through the solar field, it vaporizes and powers a steam turbine, which in turn drives a generator in the power block. The TES unit is a two-tank system with a heat exchanger between the two tanks for storing hot and cold salts.

The major technical challenges hindering the wide adoption of this technology are the enormous pressure drop across the storage and nonoptimal heat transfer from the heat transfer fluid to the storage medium and vice versa. These issues will directly and indirectly affect the overall cost (capital, operational, and maintenance costs) of the system.

The advancements in "heat exchanger" materials and coatings have a big effect on performance. This continually pushed the limits of durability and efficiency.

The cost of cleaning a heat exchanger is small compared to the cost of lost production should a heat exchanger require an unscheduled shutdown. Product or chemical deposits on heat-transfer surfaces weaken an exchanger's heat-transfer capacity and must be cleaned away regularly to maintain high performance and prevent disruption of processing.
