Capacitors used for energy storage. Capacitors are devices which store electrical energy in the form of electrical charge accumulated on their plates. When a capacitor is connected to a power source, it accumulates energy which can be released when the capacitor is disconnected from the charging source, and in this respect they are similar to batteries.

This approach should be universally applicable to designing high-performance dielectrics for energy storage and other related functionalities. Multilayer ceramic capacitors (MLCCs) have broad applications in electrical and electronic systems owing to their ultrahigh power density (ultrafast charge/discharge rate) and excellent stability (1 - 3).

Typically, after an explanation on the physics of capacitors and their energy capacity $E = \frac{1}{2} CV^2$, where C is the capacitance in farads (F), and V is the voltage, there would remarks that a capacitor on the order of one farad (F) would be impractically large, perhaps as large as a filing cabinet or small bookcase.

ESS having limited capacity in terms of both power and energy can be categorized on the basis of their response; rapid response ESS like flywheel, ultra-capacitors and li-ion batteries are called short-term while chemical battery (lead acid), pumped hydro storage and compressed air are known as long-term ESS.
