Using the detailed NREL cost models for LIB, we develop base year costs for a 60-MW BESS with storage durations of 2, 4, 6, 8, and 10 hours, shown in terms of energy capacity (\$/kWh) and power capacity (\$/kW) in Figures 1 and 2, respectively.

To convert these normalized low, mid, and high projections into cost values, the normalized values were multiplied by the 4-hour battery storage cost from Feldman et al. (2021) to produce 4-hour battery systems costs.

This inverse behavior is observed for all energy storage technologies and highlights the importance of distinguishing the two types of battery capacity when discussing the cost of energy storage. Figure 1. 2021

Current costs for utility-scale battery energy storage systems (BESS) are based on a bottom-up cost model using the data and methodology for utility-scale BESS in (Feldman et al., 2021). The bottom-up BESS model accounts for major components, including the LIB pack, inverter, and the balance of system (BOS) needed for the installation.

**Purpose of Review** As the application space for energy storage systems (ESS) grows, it is crucial to value the technical and economic benefits of ESS deployments. The Levelized Cost of Storage (LCOS) is a metric used to calculate the cost of energy storage systems per unit of energy consumed or produced. This calculation takes into account the initial costs, ongoing operational expenses, and the total amount of energy that the system can store and discharge during its operational life.

Forecast procedures are described in the main body of this report. C&C or engineering, procurement, and construction (EPC) costs can be estimated using the footprint or total volume and weight of the battery energy storage system (BESS). For this report, volume was used as a proxy for these metrics.

Base year costs for utility-scale battery energy storage systems (BESS) are based on a bottom-up cost model using the data and methodology for utility-scale BESS in (Ramasamy et al., 2022). The bottom-up BESS model accounts for major components, including the LIB pack, the inverter, and the balance of system (BOS) needed for the installation.

The lowest energy storage cost is achieved in reservoir pairs with large head and large water-to-rock (V/R) ratios for the target storage capacity. The relationships for the power component costs comprises two components--tunnel and powerhouse--which have a complex relationship with the characteristics of the site.
