Under light irradiation, the photogenerated electrons from CdS are delivered to the Ni<sub>3</sub>S<sub>2</sub> interface, where Li-ion de-intercalation occurs. The conversion and storage of solar energy have thus been achieved. It is found that, (i) light energy can indeed be stored in the Li-ion batteries as electrical energy and released reversibly.

Among various technologies of solar energy utilization, solar-thermal energy storage (STES) technologies are widely studied to counter the mismatch between supply and energy demand as solar energy is intermittent and weather-dependent 5, 6, 7.

With the aim of eventually powering small electronic devices and diverting toxic waste from landfill, researchers at Flinders University, Australia along with Chinese collaborators have used a catalysis strategy to produce two-electron storage in organic radical batteries (ORBs), which they believe is "a big advance in improving their storage capability".

The device, they say, may one day enable cheaper, large-scale energy storage. The palm-sized prototype generates three times as much power per square centimeter as other membraneless systems -- a power density that is an order of magnitude higher than that of many lithium-ion batteries and other commercial and experimental energy-storage systems.
