Rapid reclosing is achieved by storing charged energy in a separate closing spring. Safety is achieved by providing remote charging of the spring. The two-step stored energy process is designed to charge the closing spring and release energy to close the circuit breaker. It uses separate opening and closing springs.

The pressure fluctuations (PFs) were significantly different for different head pump turbines (PTs). To study the evolutionary mechanisms of PFs inside a low-head PT, the co-closing of the guide vane (GV) and ball valve after a pump power trip was simulated by adopting the one- and three-dimensional coupled approach and dynamic mesh technology.
