In SMES systems, energy is stored in dc form by flowing current along the superconductors and conserved as a dc magnetic field . The current-carrying conductor functions at cryogenic (extremely low) temperatures, thus becoming a superconductor with negligible resistive losses while it generates magnetic field.

Finding the Total Magnetic Field: Permeability and Susceptibility. Suppose that we place a material inside a magnetic field. The total magnetic field inside the material comes from two different sources: The magnetic field that was applied externally ( $B_0$ ). The magnetization of the material in response to the external field ( $B_m$ ).

In order to implement this concept it is necessary to consider the operation of several new devices in the electrical grid. A class of these potential devices is Superconducting Magnetic Energy Storage (SMES) that present, among other features, very fast response times. SMES devices can play a key role in helping to overcome several grids ...

The eq. (3) shows that the total input energy consists of two parts. The first part is energy stored in magnetic field and the second part is the energy dissipated in the circuit resistance in the form of heat. Therefore, the energy stored in the magnetic field is given by  $\mathcal{W}_f = \int_0^T e_i dt$

Superconducting magnetic energy storage (SMES) systems store energy in the magnetic field created by the flow of direct current in a superconducting coil that has been cryogenically cooled to a temperature below its superconducting critical temperature. This use of superconducting coils to store magnetic energy was invented by M. Ferrier in 1970.
