Batteries are an attractive option for grid-scale energy storage applications because of their small footprint and flexible siting. A high-temperature (700 °C) magnesium-antimony (Mg||Sb) liquid metal battery comprising a negative electrode of Mg, a molten salt electrolyte (MgCl<sub>2</sub>-KCl-NaCl), and a positive electrode of Sb is proposed and characterized.

But back to metallurgical antimony, changes in lead-acid batteries have also seen a reduced loading of antimony in lead alloys, which will accelerate a surplus secondary supply stream. A key issue for second-life antimonial lead will be dependent on the economics of refining high-purity antimony for new applications.

The liquid metal battery (LMB) is an attractive chemistry for grid-scale energy-storage applications.
