

These findings demonstrate that doping is a viable and impactful method for enhancing the performance of NCM cathode materials in next-generation lithium-ion batteries.

The W doping can relieve the structural instability of Ni-rich NCM notably, leading to improved cycling and thermal stability, , , , , , .

The results showed that the energy barrier for Ni $2+$ diffusion in F-doped NCM955-F1 increased from 0.838 to 1.686 eV, indicating a more challenging Ni $2+$ migration process with decreased cation mixing. In contrast, the energy ...

Considering the effects of doping elements on conductivity, stability, and electrode compatibility, we concluded that Au, Mg, and Te are the most suitable doping elements, along with their specific optimized ratios. These findings offer valuable insights for understanding cathode properties and optimizing battery performance. 4. Conclusions

At the atomic level, doping modifies the electrochemical properties and structural stability of NCM materials, yielding several key benefits. Firstly, doping can increase the ...

indicate that appropriate Ni doping on Co_3O_4 nanoparticles enhances their electrochemical performance, showing great potential for supercapacitor applications. Keywords Ni-doped Co_3O_4 ...

In Li-rich NCM, the K doping contributes to the improvement of electrochemical performance primarily by preventing the phase transition from a layered to a spinel structure , , , , .

Anion doping and substitution represent another effective strategy for enhancing the electrochemical performance of Ni-rich cathode materials and addressing challenges such as cation mixing and oxygen evolution. [80 - 83] For example, Kim et al. successfully synthesized an F-doped NCM811 cathode material through a solid-state reaction.

The development of advanced layered Ni-rich cathodes is essential for high-energy lithium-ion batteries (LIBs). However, the prevalent Ni-rich cathodes are still plagued by inherent issues of chemo...

Nature Communications 12, Article number: 6552 (2021) Cite this article Doping is a well-known strategy to enhance the electrochemical energy storage performance of layered cathode materials.

The synergistic effect of Al/Zr co-doping in SNCM lattice improve the Li-ion mobility, relief the internal strain, and suppress the Li/Ni cation mixing upon cycling at high cut ...

However, the multitude of doping strategies available for NCM battery systems presents a challenge in

determining the most effective approach. In this study, we elucidate the ...

7 · Considering the high price and scarcity of cobalt resource, zero-cobalt, high-nickel layered cathode material (LNM) have been considered as the most promising material for next-generation high-energy-density lithium-ion batteries (LIBs). However, current LNM faces ...

A doping strategy is of great significance to improve the structural and electrochemical properties of pristine NCM cathode materials, where dopants occupy TM or Li ...
