In deeply decarbonized energy systems utilizing high penetrations of variable renewable energy (VRE), energy storage is needed to keep the lights on and the electricity flowing when the sun isn't shining and the wind isn't blowing -- when generation from these VRE resources is low or demand is high.

MITEI's three-year Future of Energy Storage study explored the role that energy storage can play in fighting climate change and in the global adoption of clean energy grids. Replacing fossil fuel-based power generation with power generation from wind and solar resources is a key strategy for decarbonizing electricity.

Even though long-duration storage could play a critical role in enabling carbon-free or high renewable power systems, the economics of long-duration storage technologies are not well understood.

Notably, Alberta's storage energy capacity increases by 474 GWh (+157%) and accounts for the vast majority of the WECC's 491 GWh increase in storage energy capacity (from 1.94 to 2.43 TWh).

Long-duration energy storage technologies can be a solution to the intermittency problem of wind and solar power but estimating technology costs remains a challenge. New research identifies cost targets for long-duration storage technologies to make them competitive against different firm low-carbon generation technologies.
