So far, our discussions have covered elements which are either energy sources or energy dissipators. However, elements such as capacitors and inductors have the property of being able to store energy, whose V-I relationships contain either time integrals or derivatives of voltage or current. As one would suspect, this means that the response of these elements is not ...

In the following sections, we address models with two energy storage elements. The simple step of adding an additional energy storage element allows much greater variation in the types of responses we will encounter. The largest difference is that systems can now exhibit oscillations in time in their natural response.

That oscillation can be responsible for losses or malfunctioning of the DC sources (photovoltaic panels or batteries). It is also may cause efficiency reduction of photovoltaic generators. The oscillation reduction can be achieved by adding two power switches and a passive energy storage element to the converter topology.
