Capacitors used for energy storage. Capacitors are devices which store electrical energy in the form of electrical charge accumulated on their plates. When a capacitor is connected to a power source, it accumulates energy which can be released when the capacitor is disconnected from the charging source, and in this respect they are similar to batteries.

In a power backup or holdup system, the energy storage medium can make up a significant percentage of the total bill of materials (BOM) cost, and often occupies the most volume. The key to optimizing a solution is a careful selection of components so that holdup times are met, but the system is not overdesigned.

Dielectric capacitor is a new type of energy storage device emerged in recent years. Compared to the widely used energy storage devices, they offer advantages such as short response time, high safety and resistance to degradation. However, they do have a limitation in terms of energy storage density, which is relatively lower.

The discharged energy-storage density ( $W_D$ ) can also be directly detected by charge-discharge measurements using a specific circuit. The capacitor is first charged by external bias, and then, through a high-speed and high-voltage switch, the stored energy is discharged to a load resistor ( $R_L$ ) in series with the capacitor. The current passed through the resistor  $I(t)$  or ...
